ACUTE KIDNEY INJURY (AKI)

Nephrology unit
Mansoura Faculty of Medicine
Definitions:

A rapid deterioration of parenchymal renal functions sufficiently severe to result in uremia.

- Usually but not invariably reversible.
- Oliguria is usually, but not invariably a feature.

Recently the term AKI has replaced the term ARF.
RIFLE Criteria

- The RIFLE criteria consists of three graded levels of injury (Risk, Injury, and Failure).
- Based upon either the magnitude of elevation in serum creatinine or urine output.
- Two outcome measures (Loss and End-stage renal disease)
- The RIFLE strata are as follows
Proposed classification scheme for acute renal failure (ARF)

- **Risk**
  - Increased SCR x 1.5 or GFR decrease > 25%

- **Injury**
  - Increased SCR x 2 or GFR decrease > 50%

- **Failure**
  - Increase SCR x 3 or GFR decrease 75% OR SCR ≥ 24 mg/dL
    - Acute rise ≥ 0.5 mg/dL
  - UO < 0.5 ml/kg/h x 6 hr

- **Loss**
  - Persistent ARF** = complete loss of kidney function > 4 weeks
  - End Stage Kidney Disease (≥ 3 months)
  - UO < 0.3 ml/kg/h x 24 hr or Anuria x 12 hrs

**Urine Output Criteria**

- **High Sensitivity**
  - UO < 0.5 ml/kg/h x 6 hr
  - UO < 0.5 ml/kg/h x 12 hr

- **High Specificity**
  - UO < 0.3 ml/kg/h x 24 hr or Anuria x 12 hrs
  - Oliguria
### Definition of Acute Kidney Injury (AKI) based on “Acute Kidney Injury Network”

<table>
<thead>
<tr>
<th>Stage</th>
<th>Increase in Serum Creatinine</th>
<th>Urine Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.5-2 times baseline OR 0.3 mg/dl increase from baseline</td>
<td>&lt;0.5 ml/kg/h for &gt;6 h</td>
</tr>
<tr>
<td>2</td>
<td>2-3 times baseline</td>
<td>&lt;0.5 ml/kg/h for &gt;12 h</td>
</tr>
<tr>
<td>3</td>
<td>3 times baseline OR 0.5 mg/dl increase if baseline &gt; 4 mg/dl OR Any RRT given</td>
<td>&lt;0.3 ml/kg/h for &gt;24 h OR Anuria for &gt;12 h</td>
</tr>
</tbody>
</table>
AKI is defined as any of the following:

- Increase in SCr by X0.3 mg/dl within 48 hours; or
- Increase in SCr to X1.5 times baseline, which is known or presumed to have occurred within the prior 7 days; or
- Urine volume <0.5 ml/kg/h for 6 hours.

* Must have met initial criteria for definition of AKI

Classification of AKI
CAUSES OF ACUTE RENAL FAILURE

1. Prerenal
   Sudden and severe drop in blood pressure (shock) or interruption of blood flow to the kidneys from severe injury or illness

2. Intrarenal
   Direct damage to the kidneys by inflammation, toxins, drugs, infection, or reduced blood supply

3. Postrenal
   Sudden obstruction of urine flow due to enlarged prostate, kidney stones, bladder tumor, or injury
Types of Acute Renal Failure

**Prerenal**, caused by transient renal hypoperfusion due to:
- Hypotension
- Decreased cardiac output
- Decreased effective arterial blood volume

**Postrenal**, due to obstruction of the urinary tract.

**Intrinsic**

**Acute glomerulonephritis** involves inflammation and damage to the glomerular membrane.

**Acute interstitial nephritis**, an allergic reaction, may be caused by a variety of drugs.

**Acute tubular necrosis** accounts for more than 50% of cases of acute renal failure.

*Causes:* nephrotoxic agents, prolonged renal hypoperfusion.
In pre-renal:

- Renal tissue is intact
- Kidney biopsy shows normal renal histology.
- Oliguria and high serum creatinine are due to functional impairment.

- Since there is no structural renal damage, early diagnosis and correction of renal hypoperfusion results in immediate diuresis and rapid drop in serum creatinine and blood urea levels.

- If hypoperfusion is severe or neglected, renal compensatory mechanisms will fail and acute tubular necrosis occurs.
In post-renal

- The obstruction of the urinary tract results in increasing the pressure above the level of the obstruction.

- When this back pressure exceeds that of the filtration pressure in the renal glomeruli, the process of urine formation will stop with progressive accumulation of wastes and increase of serum creatinine and blood urea.
Intrinsic Renal

- This includes:
  - Acute tubular necrosis (ATN)
  - Acute interstitial nephritis
  - Acute glomerulonephritis
Acute Kidney Injury

- Pre-renal
- Intrinsic Renal
  - Acute glomerulo nephritis (5%)
- Post-renal
  - Acute tubular necrosis (85%)
  - Acute interstitial nephritis (10%)
    - Toxic
    - Ischaemic
    - Combined
Acute tubular necrosis (ATN)
Acute Tubular Necrosis

ATN can be induced by:

- Renal hypoperfusion (ischemia)
- Exposure to nephrotoxins (exogenous or endogenous toxins)
- A combination of both.
Causes of Ischaemic ATN:

A- Blood Loss
• Haemorrhage (post partum, surgical or gastrointestinal).
• Major trauma

B- Fluid Loss
• Gastrointestinal (vomiting or diarrhoea)
• Renal (aggressive diuresis or polyuria)

C- Third Space
• Haematoma
• Illius
• Peritonitis

D- Severe vasodilatation as in septicemia, rapid edema formation, liver cell failure.

E- Renovascular disease
• Renal artery occlusion by stenosis, embolism or compression.
• Renal vein thrombosis or compression.
Causes of Toxic ATN

(A) Exogenous nephrotoxins include:

Antibiotics:
- Aminoglycosides
- Amphotericin B
- Cephalosporin
- Acyclovir
- Sulfonamide
- Tetracyclines

Anaesthetic agents:
- Methoxyflurane

Contrast Media:

Analgesics:
- Phenacetin

Metals:
- Mercury, lead, arsenic, bismuth, cadmium, antimony

Organic solvents:
- Glycols

Poisons:
- Snake bite, stings, bacterial toxins.

(B) Endogenous nephrotoxins include

Pigments:
- Myoglobin
- Hemoglobin
- Methemoglobin

Crystals:
- Uric acid
- Calcium
- Oxalate
**Acute tubular necrosis** Light micrograph in acute tubular necrosis showing focal loss of tubular epithelial cells (arrows) and partial occlusion of tubular lumens by cellular debris (D). Courtesy of Helmut Rennke, MD.
Acute cortical necrosis:

- Is a subset of ATN in which there is a massive necrosis of the tubules and glomeruli of the renal cortex.
- The condition may be focal or diffuse with irreversible damage of the kidneys.
- It is suspected when ATN fails to recover after 4-6 weeks.
- Acute cortical necrosis usually occurs with complicated pregnancy as postpartum hemorrhage and abruptio placenta
Clinical features of AKI
Usually, the patient gives history of the etiologic cause such as:

- Trauma
- Shock
- Hemolysis
- Drug intake
- Infection
- Stone disease
- Procedure requiring contrast media
- ICU admission
Careful history is essential

- Exposure to nephrotoxins and drugs
- Anuria may indicate post-renal causes
- Skin rashes may indicate allergic nephritis
- Evidences of vomiting
- Pelvic and perineal pain of abortion
- Ischemia or trauma
- Rhabdomyolysis

- A history of prostatic disease, nephrolithiasis
- Recent surgical or radiologic procedures
- Past and present use of medications
- Family history of renal diseases
Patient may notice a change in

1. Urine volume and character
2. Oliguria is common, but in 10-50% of cases urine volume will be normal or even higher (Non-oliguric).
3. Absolute anuria is highly suggestive of obstructive AKI (post-renal) or very severe form of ATN (cortical necrosis).
Manifestation of salt and water retention

- Edema
- Puffiness
- Hypertension
- Heart failure
Manifestations of uremia

By time, manifestations of uremia appear as: acidotic breathing, dyspnea, nausea, vomiting, headache, muscle twitches and even frank encephalopathy and coma.

Patient may present as well with complications
Complications of AKI
Cardiovascular
- pulmonary oedema
- hypertension
- myocardial infarction
- arrhythmias
- pericardial effusion
- pulmonary embolism

Metabolic
- hyponatremia
- acidosis
- hyperphosphatemia
- hyperkalemia
- hypocalcemia

Neurologic
- coma
- seizures

Gastrointestinal
- gastritis
- gastroduodenal ulcers

Haematologic
- anaemia
- hemorrhagic diathesis

Infections
- pneumonia
- septicemia
- UTI

Investigations of AKI
A- Urinary indices:-

May be helpful in the differentiation between pre-renal failure and acute tubular necrosis.

Diuretics should not be given during the preceding 48 hours for these parameters to be valid.
Guidelines for urinary indices whereby established ARF can be distinguished from renal vasoconstriction with intact tubular function (prerenal azotemia)

<table>
<thead>

Osm, osmole; Eq, equivalent.
B- Urinary sediment:

Centrifugation of fresh urine sample and examination of the urinary sediment may be helpful in diagnosing different causes of AKI.

In pre-renal failure and in ischaemic ATN urinary sediment is usually free.

Urine sediment in Acute Nephrotic Syndrome and in RPGN is characteristic.
Urine Examination

Urinary Sediment in AKI

Normal or few RBC or WBC or hyaline casts

- RBC
  - RBC Casts
    - Prerenal
      - Postrenal
        - Arterial thrombosis or embolism
        - Preglomerular vasculitis
        - HUS or TTP
        - Scleroderma crisis
    - GN
      - Vasculitis
      - Malignant hypertension
      - Thrombotic microangiopathy
    - Interstitial nephritis
    - GN Pyelonephritis
    - Allograft rejection
    - Malignant infiltration of the kidney
  - WBC
    - WBC Casts
    - RTE Cells
      - RTE Casts Pigmented casts
    - ATN Tubulo-interstitial nephritis
    - Acute cellular allograft rejection
    - Myoglobinuria
    - Hemoglobinuria
  - Granular casts
  - Eosinophiluria
  - Crystalluria

Abnormal
C- Renal Imaging:

1. Plain film of the abdomen:
This will show kidney parity, size, shape, calcification and stones.

2. Renal Ultrasonography and Echo-Doppler of renal vs:
   ◦ US safely assesses kidney size, shape and echogenicity.
   ◦ Cortical thinning or oedema can sometimes be seen clearly.
   ◦ Also, it can exclude obstructive uropathy (back pressure changes).

Echo-Doppler of renal vessels can exclude occlusion of the renal arteries and veins.

3. Retrograde and antegrade pyelography:
   Provide the most reliable information on the patency of the ureter.
Role of Ultrasound
4. **Angiography:**

Is useful mainly when an acute reversible renovascular event is suspected such as **embolization, thrombosis or involvement in a dissecting aortic aneurysm.** It carries the risk of exposure to contrast media which could be nephrotoxic.

5. **C.T. studies:**

Provide reliable information on kidney parity, size, shape and presence of hydronephrosis.

6. **Magnetic Resonance urography:**

*Recently MRI urography (MRU) without use of contrast media can provide films similar to IVP.*

*It is thus of great value to exclude U.T. obstruction without the risk of contrast media nephropathy.*

*It is important to know that Gadolinium an MRI contrast is nephrotoxic.*
MR urography shows bilateral hydroureteronephrosis in a patient with 4.8 mg/dl serum creatinine (IVU is not feasible). Note the hypointense ureteric stone bilaterally (arrows).
D. Renal biopsy:

Indications

- Urine: RC cast, WC cast, Proteinuria
- Unexplained
- Systemic disease
- Prolonged course (more than 3 weeks).
TREATMENT OF AKI
A-Treatment of the cause

e.g. any condition causing renal hypoperfusion, exposure to toxic drug or chemical or systemic disease.
B- Conservative measures:

I - fluid balance:

- Careful monitoring of intake/output and body weight is very important to avoid overload and hypovolemia.
  
  The 1st may lead to pulmonary edema while the 2nd may aggravate renal ischemia.

- Patient should receive fluids =
  
  *daily urine output + other sensible losses* e.g. vomitus or diarrhea + amount equals the *insensible loss* which is around 600 c.c. for 60kg body weight patient.

- Fluids could be given orally or (if not possible), it could be given intravenously.
2- Electrolytes and acid-base balance:

- Prevent and treat hyperkalemia.
- Avoid hyponatremia.
- Keep serum bicarbonate above 16 mmol/L.
- Minimize hyperphosphatemia by giving phosphate binders (e.g. Ca Co3 & AL hydroxide) with meals.
- Treat hypocalcaemia.

3- Treatment of hyperkalemia:

- Calcium gluconate I.V.
- Glucose 50% + Insulin
- Na Hco3 I.V.
- K-exchange resins (e.g. resonium)
- Avoid diets and drugs causing hyperkalaemia
- Dialysis
4- **Nutritional support:**
- With rare exceptions, Na & K restriction is appropriate.
- The place of dietary ptn restriction is controversial:
  - Hope to avoid dialysis → 40gm/day
  - Pt treated with HD → 70gm/day
  - Hypercatabolic pt will need ↑ nitrogen intake

5- **Drugs:**
- Review all medications.
- Adjust dosage for renal failure.
The indications of dialysis in AKI are:

**a. Clinical:**
- Poor clinical state, nausea, confusion.
- Fluid overload, pulmonary oedema.
- Preoperatively.

**b. Biochemical:**
- Plasma K+ > 7 mmol/L.
- Plasma bicarbonate < 12 mmol/L
- Arterial pH < 7.15.
Prevention of AKI
The timing of intervention to prevent ATN is important. Protective agents must be administered at the time of, or immediately following potential renal insult. This intervention may prevent or at least blunt the severity of ATN.

The intervention could be through the following approaches. In different combinations according to the clinical situation:

- Volume expansion by isotonic saline loading.
- Diuretic as furosemide (to change ATN to polyuric-easy manageable type)
- Non dihydropyridine Calcium channel blockers as Verapamil.
- Vasodilating agents as dopamine in renal dose 1-2 ug/kg/min. (are not effective).
In case of contrast media, the following additional points should be adopted, these are:-

- Avoid unnecessary contrast procedures.
- Avoid multiple contrast exposure within a few days.
- Avoid contrast exposure in high risk patient.
- Use the smallest dose possible.
- Use non-ionic, low viscosity contrast (good evidence).
- Hydration by isotonic saline in a dose of 3ml/kg/h. for 12h before and after contrast exposure (has the best evidence).
- Acetyl cysteine sachets 600mg/kg tds, 2 days before and after exposure (good evidence).
- Washing the contrast out immediately after the technique (e.g. coronary angiography) by hemodialysis, is of no value.
Prognosis of AKI
The mortality of AKI remains high, ranging between 50-80% in surgical and post-traumatic cases.

It is generally lower in AKI due to drugs and toxins.

About 75% of deaths occur in the first week of AKI, and 25-50% of these deaths are due to the underlying disease.

The overall prognosis is better in non-oliguric than in oliguric renal failure.

The factors influencing patient survival in AKI include the following:

- Etiology of AKI.
- Severity of AKI.
- Number and severity of coexisting illness.
- Patient's age.
- Presence of complications
THANK YOU
